Streaming movies online is free Watch Crook: It's Good To Be Bad (2010) movie with HD streaming Download Crook: It's Good To Be Bad (2010) full movie, putlocker, Yify, seeso, streamango and many more. Q: Which is more efficient to consider: "1 table vs. 1 column vs. 10 columns vs. 30 columns" or just consider the columns? I have to make some calculations that depend on the values stored in many different tables. There are only three of these tables: Primary, Secondary, and Other. All of these tables have the same structure - it's basically just "Column1, Column2, Column3,... ColumnN". My question is, should I create a single table and just make it a Many-To-Many relationship with Primary and Secondary? Or should I do separate tables for each column? What's the best design for this situation, considering the speed of the calculations I'm trying to make? A: What you're doing is called "EAV" (Entity-Attribute-Value), where you have a 1:N relationship between entities (tables) and attributes. Using separate tables will certainly make it more manageable (and readable), but the downside is that you will have to join a dozen of tables just to have a single result. Another option would be to have one table with a unique key (just a surrogate key), and use the ID to reference the data from the other tables. This option would probably be more efficient, but you'll have the headache of maintaining all the IDs manually. My current open-office setup has Mac Office 2007, a iMac, and a PC. The Mac Office 2007 has been working fine so far, but this evening, when I try to open the Word document I was
