Field of the Invention The present invention relates to an output circuit for a semiconductor integrated circuit device, and more particularly to an output circuit having an output buffer circuit of a

---

cascode output stage structure. 2. Description of the Prior Art A conventional output circuit of this kind has an output buffer circuit of a cascode output stage structure to drive a load. The output buffer circuit is constructed of a P channel MOS transistor (hereinafter referred to as PMOS) for use as a constant current source and an N channel MOS transistor (hereinafter referred to as NMOS) for use as a load. The drain of the PMOS is connected to the drain of the NMOS, and the output terminal of the output circuit is connected to the gate of the NMOS. In general, the operation of this output circuit is controlled by a drive signal of an output circuit control circuit. The conventional output circuit is usually constructed of a circuit using PNP bipolar transistors. This construction, however, requires an addition of a bipolar chip such as a bipolar transistor or a current mirror circuit, and thus complicates the construction of the output circuit. In addition, the use of the bipolar chip requires the preparation of an output buffer circuit separately from an output circuit control circuit in order to prevent the output buffer circuit from being affected by noise generated from the control circuit. Q: When can you
