The polyphenylene ether resins are used in applications wherein their excellent heat resistance, mechanical properties, processability and electrical characteristics are utilized. The inventions of the polyphenylene ethers have been known for the last three decades. The earliest process for their preparation being the oxidative coupling of biphenyls as described in U.S. Pat. No. 3,306,874. Recently, the polymerization of dihalo alkanes such as tetrachloro- and trifluoroethane in the presence of molecular oxygen and a metallic catalyst such as cuprous chloride or a complex oxide of copper, phosphorus, magnesium and oxygen to produce the polyphenylene ether is well known and is illustrated by Hay et al in U.S. Pat. No. 3,306,874, by Basil et al in U.S. Pat. No. 3,379,792, by Bussink et al in U.S. Pat. No. 3,354,163 and by Smith in U.S. Pat. No. 3,306,874. In these earlier processes, copper acetate, copper trifluoroacetate, cuprous bromide, cupric bromide and cupric acetate were used as catalysts and an accelerator to produce polymers of relatively low molecular weight. To produce polymer of higher molecular weight, such as that having a molecular weight of about 20,000 to 50,000, a hydrogen halide or a metal chloride such as cupric chloride, cupric bromide or cuprous bromide and certain oxidation promoters, such as phenol, isopropanol or aromatic amines, were employed. Such reactions to produce polyphenylene ethers have been reviewed by Morrison, "Recent Progress in Phenolic Resins," in Encyclopedia of Polymer Science and Technology, 2nd edition, volume 4, pages 403-424, (1969). In the processes in which the molecular weight
